## Preliminaries

■ Consider the following integer linear program (ILP):

$$
z_{I P}=\min _{x \in \mathcal{F}}\left\{c^{\top} x\right\}=\min _{x \in \mathcal{P}}\left\{c^{\top} x\right\}=\min _{x \in \mathbb{Z}^{n}}\left\{c^{\top} x: A x \geq b\right\}
$$

where

$$
\begin{array}{rlrl}
\mathcal{F} & =\left\{x \in \mathbb{Z}^{n}: A^{\prime} x \geq b^{\prime}, A^{\prime \prime} x \geq b^{\prime \prime}\right\} & \mathcal{Q} & =\left\{x \in \mathbb{R}^{n}: A^{\prime} x \geq b^{\prime}, A^{\prime \prime} x \geq b^{\prime \prime}\right\} \\
\mathcal{F}^{\prime}=\left\{x \in \mathbb{Z}^{n}: A^{\prime} x \geq b^{\prime}\right\} & \mathcal{Q}^{\prime} & =\left\{x \in \mathbb{R}^{n}: A^{\prime} x \geq b^{\prime}\right\} \\
& \mathcal{Q}^{\prime \prime} & =\left\{x \in \mathbb{R}^{n}: A^{\prime \prime} x \geq b^{\prime \prime}\right\}
\end{array}
$$

■ Denote $\mathcal{P}=\operatorname{conv}(\mathcal{F})$ and $\mathcal{P}^{\prime}=\operatorname{conv}\left(\mathcal{F}^{\prime}\right)$.

- $O P T(c, X)$ : Subroutine returns $x \in X$ that minimizes $c^{\top} x$.

■ $S E P(x, X)$ : Subroutine returns $(a, \beta)$ which separates $x$ from $X$ (if exists).

- Outline

## Decomposition Methods

## - Preliminaries

## Preliminaries

- Assumption:
- $\operatorname{OPT}(c, \mathcal{P})$ and $S E P(x, \mathcal{P})$ are "hard".
- $O P T\left(c, \mathcal{P}^{\prime}\right)$ and $\operatorname{SEP}\left(x, \mathcal{P}^{\prime}\right)$ are "easy".
- $\mathcal{Q}^{\prime \prime}$ can be represented explicitly (description has polynomial size).
- $\mathcal{P}^{\prime}$ must be represented implicitly (description has exponential size).

■ Classical Example - Traveling Salesman Problem

$$
\begin{array}{ll}
\sum_{e \in \delta(u)} x_{e}=2 & \forall u \in V \\
\sum_{e \in \delta(S)} x_{e} \geq 2 & \forall S \subset V, 2 \leq|S| \leq|V|-1 \\
x_{e} \in\{0,1\} & \\
& \forall e \in E
\end{array}
$$

- One classical decomposition of TSP is to look for a spanning subgraph with $|V|$ edges ( $\mathcal{P}^{\prime}=1$-Tree) that satisfies the 2-degree constraints ( $\mathcal{Q}^{\prime \prime}$ ).

## Example - Polyhedra

$$
\begin{aligned}
& \text { min } \\
& \begin{array}{rlll}
x_{1} & & \\
7 x_{1}-x_{2} & \geq 13 & (1) \\
x_{2} & \geq 1 & (2) \\
-x_{1}+x_{2} & \geq & -3 & (3) \\
-x_{2} & \geq & -5 & (4) \\
0.2 x_{1}-x_{2} & \geq & -4 & (5) \\
-x_{1}-x_{2} & \geq & -8 & (6) \\
-0.4 x_{1}+x_{2} & \geq & 0.3 & (7) \\
x_{1}+x_{2} & \geq & 4.5 & (8) \\
3 x_{1}+x_{2} & \geq 9.5 & (9) \\
0.25 x_{1}-x_{2} & \geq & -3 & (10) \\
& x \in \mathbb{Z}^{2} & (11)
\end{array} \\
& \mathcal{Q}^{\prime}=\left\{x \in \mathbb{R}^{n} \mid x \text { satisfies }(1)-(5)\right\} \\
& \mathcal{Q}^{\prime \prime}=\left\{x \in \mathbb{R}^{n} \mid x \text { satisfies (6) - (10) }\right\} \\
& \mathcal{P}^{\prime}=\operatorname{conv}\left(\mathcal{Q}^{\prime} \cap \mathbb{Z}^{n}\right)
\end{aligned}
$$

## Bounding

■ Goal: Compute a lower bound on $z_{I P}$ by building an approximation to $\mathcal{P}$.

- The most straightforward approach is to use the continuous approximation

$$
z_{L P}=\min _{x \in \mathcal{Q}}\left\{c^{\top} x\right\}=\min _{x \in \mathbb{R}^{n}}\left\{c^{\top} x: A^{\prime} x \geq b^{\prime}, A^{\prime \prime} x \geq b^{\prime \prime}\right\}
$$

- Decomposition approaches attempt to improve on this bound by utilizing the fact that $O P T\left(c, \mathcal{P}^{\prime}\right)$ or $\operatorname{SEP}\left(x, \mathcal{P}^{\prime}\right)$ is easy.

$$
z_{D}=\min _{x \in \mathcal{P}^{\prime}}\left\{c^{\top} x \mid A^{\prime \prime} x \geq b^{\prime \prime}\right\}=\min _{x \in \mathcal{F}^{\prime} \cap \mathcal{Q}^{\prime \prime}}\left\{c^{\top} x\right\}=\min _{x \in \mathcal{P}^{\prime} \cap \mathcal{Q}^{\prime \prime}}\left\{c^{\top} x\right\} \geq z_{L P}
$$

■ $\mathcal{P}^{\prime}$ is represented implicitly through solution of a subproblem.

DECOMP Framework

## Cutting Plane Method

■ Cutting Plane Method (CPM) gives an approximation of $\mathcal{P}$ by building an outer approximation of $\mathcal{P}^{\prime}$ intersected with $\mathcal{Q}^{\prime \prime}$.
■ Let $[D, d]$ denote the facets of $\mathcal{P}^{\prime}$, so that

$$
\mathcal{P}^{\prime}=\left\{x \in \mathbb{R}^{n}: D x \geq d\right\}
$$

## Cutting Plane Method

1. Initialize: Form outer approximation with $\left[D^{0}, d^{0}\right]=\left[A^{\prime \prime}, b^{\prime \prime}\right]$ and set $t \leftarrow 0$.

$$
\mathcal{P}_{O}^{0}=\left\{x \in \Re^{n} \mid D^{0} x \geq d^{0}\right\} \supseteq \mathcal{P}^{\prime} \cap \mathcal{Q}^{\prime \prime}
$$

2. Master Problem: Solve an LP to obtain an optimal primal solution $x_{C P}^{t}$.

$$
z_{C P}^{t}=\min _{x \in \Re}{ }^{n}\left\{c^{\top} x \mid D^{t} x \geq d^{t}\right\}
$$

3. Subproblem: Call $\operatorname{SEP}\left(x_{C P}^{t}, \mathcal{P}^{\prime}\right)$ to generate improving v.i.s for $\mathcal{P}$, violated by $x_{C}^{t}$.
4. Update: If found, form a new outer approximation, set $t \leftarrow t+1$ and goto step 2.

$$
\mathcal{P}_{O}^{t+1}=\left\{x \in \Re^{n} \mid D^{t+1} x \leq d^{t+1}\right\} \supseteq \mathcal{P}
$$

- The method converges to the bound

$$
z_{C P}=c^{\top} \hat{x}_{C P}=z_{D}
$$

## Cutting Plane Method

(a)

(b)

## Dantzig-Wolfe Decomposition

■ Dantzig-Wolfe Decomposition (DW) gives an approximation of $\mathcal{P}$ by building an inner description of $\mathcal{P}^{\prime}$ intersected with $\mathcal{Q}^{\prime \prime}$.
■ Let $\mathcal{E}$ denote the extreme points of $\mathcal{P}^{\prime}$, so that

$$
\mathcal{P}^{\prime}=\left\{x \in \Re^{n} \mid x=\sum_{s \in \mathcal{E}} s \lambda_{s}, \sum_{s \in \mathcal{E}} \lambda_{s}=1, \lambda_{s} \geq 0 \forall s \in \mathcal{E}\right\} .
$$

## Dantzig-Wolfe Decomposition

1. Initialize: Form inner approximation with $\mathcal{E}^{0} \subset \mathcal{E}$ and set $t \leftarrow 0$.

$$
\mathcal{P}_{I}^{0}=\left\{x \in \Re^{n} \mid x=\sum_{s \in \mathcal{E}^{0}} s \lambda_{s}, \sum_{s \in \mathcal{E}^{0}} \lambda_{s}=1, \lambda_{s} \geq 0 \forall s \in \mathcal{E}^{0}\right\} \subseteq \mathcal{P}^{\prime}
$$

2. Master Problem: Solve the DW-LP to obtain optimal dual solution $\left(u_{D W}^{t}, \alpha_{D W}^{t}\right)$.

$$
\bar{z}_{D W}^{t}=\min _{\lambda \in \Re_{+} \mathcal{E}^{t}}\left\{c^{\top}\left(\sum_{s \in \mathcal{E}^{t}} s \lambda_{s}\right) \mid A^{\prime \prime}\left(\sum_{s \in \mathcal{E}^{t}} s \lambda_{s}\right) \geq b^{\prime \prime}, \sum_{s \in \mathcal{E}^{t}} \lambda_{s}=1\right\}
$$

3. Subproblem: Call $O P T\left(c^{\top}-\left(u_{D W}^{t}\right)^{\top} A^{\prime \prime}, \mathcal{P}^{\prime}\right)$, to generate improving e.p.s with reduced cost $r c(s)=\left(c^{\top}-\left(u_{D W}^{t}\right)^{\top} A^{\prime \prime}\right) s-\alpha_{D W}^{t}<0$.
4. Update: If found, form a new inner approximation, set $t \leftarrow t+1$ and goto Step 2.

$$
\mathcal{P}_{I}^{t+1}=\left\{x \in \Re^{n} \mid x=\sum_{s \in \mathcal{E}^{t+1}} s \lambda_{s}, \sum_{s \in \mathcal{E}^{t+1}} \lambda_{s}=1, \lambda_{s} \geq 0 \forall s \in \mathcal{E}^{t+1}\right\} \subseteq
$$

- The method converges to the bound

$$
z_{D W}=c^{\top}\left(\sum_{s \in \mathcal{E}} s \hat{\lambda}_{s}\right)=c^{\top} \hat{x}_{D W}=z_{D}
$$

## Dantzig-Wolfe Decomposition

## Lagrangian Relaxation

■ Lagrangian Relaxation (LD) formulates a relaxation to the original ILP as finding the minimal extreme point of $\mathcal{P}^{\prime}$ with respect to a cost which is penalized if the point lies outside of $\mathcal{Q}^{\prime \prime}$.

- The Lagrangian Dual is a piecewise-linear concave function

$$
z_{L D}=\max _{u \in \mathbb{R}_{+}^{m \prime \prime}}\left\{\min _{s \in \mathcal{E}}\left\{c^{\top} s+u^{\top}\left(b^{\prime \prime}-A^{\prime \prime} s\right)\right\}\right\}
$$

■ Rewriting LD as an LP gives the dual of the DW-LP.

$$
z_{L D}=\max _{\alpha \in \mathbb{R}, u \in \mathbb{R}_{+}^{m^{\prime \prime}}}\left\{\alpha+b^{\prime \prime \top} u \mid \alpha \leq\left(c^{\top}-u^{\top} A^{\prime \prime}\right) s \forall s \in \mathcal{E}\right\} .
$$

- So, $z_{L D}=z_{D W}$ and Lagrangian Relaxation also achieves the bound $z_{D}$.

## Lagrangian Relaxation

1. Initialize: Define $s^{0} \in \mathcal{E}$, initialize dual multipliers $u_{L D}^{0}$ for $\left[A^{\prime \prime}, b^{\prime \prime}\right]$ and set $t \leftarrow 0$.
2. Master Problem: Update the dual multipliers using directional information from $s^{t}$.
3. Subproblem: Call the subroutine $O P T\left(c-\left(u_{L D}^{t}\right)^{\top} A^{\prime \prime}, \mathcal{P}^{\prime}\right)$, to obtain a new direct $s^{t+1} \in \mathcal{E}$. If the stopping criterion is not met, go to Step 2 .

- Preliminaries
- Example - Polyhedra
- Bounding
- Example - Polyhedra
- Cutting Plane Method
- Cutting Plane Method
- Dantzig-Wolfe Decomposition
- Dantzig-Wolfe Decomposition
- Lagrangian Relaxation

## Common Framework

- The continuous approximation of $\mathcal{P}$ is formed as the intersection of two explicitly defined polyhedra (both with a small description).

$$
z_{L P}=\min _{x \in \mathbb{R}^{n}}\left\{c^{\top} x \mid x \in \mathcal{Q}^{\prime} \cap \mathcal{Q}^{\prime \prime}\right\}
$$

- Decomposition Methods form an approximation as the intersection of one explicitly defined polyhedron (with a small description) and one implicitly defined polyhedron (with a large description).

$$
z_{D}=\min _{x \in \mathbb{R}^{n}}\left\{c^{\top} x \mid x \in \mathcal{P}^{\prime} \cap \mathcal{Q}^{\prime \prime}\right\} \geq z_{L P}
$$

- Each of the traditional decomposition methods contain two primary steps
- Master Problem: Update the primal or dual solution information.
- Subproblem: Update the approximation of $\mathcal{P}: S E P\left(x, \mathcal{P}^{\prime}\right)$ or $O P T\left(c, \mathcal{P}^{\prime}\right)$.
- Integrated Decomposition Methods form an approximation as the intersection of two implicitly defined polyhedra (both with a large description).
■ So, we improve on the bound $z_{D}$ by building both an inner approximation $\mathcal{P}_{I}$ of $\mathcal{P}^{\prime}$ intersected with some outer approximation $\mathcal{P}_{O} \subset \mathcal{Q}^{\prime \prime}$.

DECOMP Framework

## Integrated Decomposition Methods

## Price and Cut

- Price and Cut (PC) gives an approximation of $\mathcal{P}$ by building an inner description of $\mathcal{P}^{\prime}$ (as in DW) intersected with an outer approximation of $\mathcal{P}$.

## Price and Cut

1. Initialize: Form inner approximation with $\mathcal{E}^{0} \subset \mathcal{E}$, an outer approximation with

$$
\begin{aligned}
& {\left[D^{0}, d^{0}\right]=\left[A^{\prime \prime}, b^{\prime \prime}\right] \text { and set } t \leftarrow 0} \\
& \mathcal{P}_{I}^{0}=\left\{x \in \Re^{n} \mid x=\sum_{s \in \mathcal{E}^{0}} s \lambda_{s}, \sum_{s \in \mathcal{E}^{0}} \lambda_{s}=1, \lambda_{s} \geq 0 \forall s \in \mathcal{E}^{0}\right\} \subseteq \mathcal{P}^{\prime} \\
& \mathcal{P}_{O}^{0}=\left\{x \in \Re^{n} \mid D^{0} x \geq d^{0}\right\} \supseteq \mathcal{P}
\end{aligned}
$$

2. Master Problem: Solve the DW-LP to obtain the optimal dual solution $\left(u_{P C}^{t}, \alpha_{P C}^{t}\right)$ the optimal decomposition $\lambda_{P C}^{t} \in \Re^{\mathcal{E}}$, which yields the optimal primal solution $x_{F}^{t}$

$$
\bar{z}_{P C}^{t}=\min _{\lambda \in \mathbb{R}_{+}^{\mathcal{E}}}\left\{c^{\top}\left(\sum_{s \in \mathcal{E}^{t}} s \lambda_{s}\right) \mid D^{t}\left(\sum_{s \in \mathcal{E}^{t}} s \lambda_{s}\right) \geq d^{t}, \sum_{s \in \mathcal{E}^{t}} \lambda_{s}=1\right\}
$$

3. Do either (a) or (b).
(a) Pricing Subproblem and Update: Call $\operatorname{OPT}\left(c^{\top}-\left(u_{P C}^{t}\right)^{\top} D^{t}, \mathcal{P}^{\prime}\right)$, to generate improving e.p.s with $r c(s)<0$. If found, form a new inner approximation $\mathcal{P}_{I}^{t+1}$ $t \leftarrow t+1$ and go to Step 2.
(b) Cutting Subproblem and Update: Call $S E P\left(x_{P C}^{t}, \mathcal{P}\right)$ to generate improving v.i.s. found, form a new outer approximation $\mathcal{P}_{O}^{t+1}$, set $t \leftarrow t+1$ and go to Step 2.

DECOMP Framework

## Relax and Cut

- Relax and Cut (RC) improves on the bound $z_{D}$ using LD and augmenting the multiplier space with valid inequalities that are violated by the solution to the Lagrangian subproblem.

## Relax and Cut

1. Initialize: Define $s^{0} \in \mathcal{E},\left[D^{0}, d^{0}\right]=\left[A^{\prime \prime}, b^{\prime \prime}\right]$, initialize dual multipliers $u_{L D}^{0}$ for $\left[D^{0}\right.$ and set $t \leftarrow 0$.
2. Master Problem: Update the dual multipliers using directional information from $s^{t}$.
3. Do either (a) or (b).
(a) Pricing Subproblem: Call the subroutine $O P T\left(c-\left(u_{L D}^{t}\right)^{\top} D^{t}, \mathcal{P}^{\prime}\right)$, to obtain a 1 direction $s^{t+1} \in \mathcal{E}$. If the stopping criterion is not met, go to Step 2.
(b) Cutting Subproblem: Call the subroutine $\operatorname{SEP}\left(s^{t}, \mathcal{P}\right)$ to generate improving v.i.s found, add them to $\left[D^{t}, d^{t}\right]$ along with new dual multipliers, and go to Step 2.

DECOMP Framework

## Structured Separation

■ In general, the complexity of $\operatorname{OPT}(c, X)=S E P(x, X)$.
■ Observation: Restrictions on the input or output of these subroutines can change their complexity.

- Template Paradigm, restricts the output of $\operatorname{SEP}(x, X)$ to valid inequalities $(a, \beta)$ that conform to a certain structure. This class of inequalities forms a polyhedron $C \supset X$.
- For example, let $\mathcal{P}$ be the convex hull of solutions to the TSP.
- $\operatorname{SEP}(x, \mathcal{P})$ is $N P$-Complete.
- $\operatorname{SEP}(x, \mathcal{C})$ is polynomially solvable, for $\mathcal{C} \supset \mathcal{P}$ the Subtour Polytope (Min-Cut) or Blossom Polytope (Padberg-Rao).
- Structured Separation, restricts the input of $\operatorname{SEP}(x, X)$, such that $x$ conforms to some structure. For example, if $x$ is restricted to solutions to a combinatorial problem, then separation often becomes much easier.

## Example - TSP

■ Traveling Salesman Problem Formulation:

$$
\begin{array}{ll}
x(\delta(u))=2 & \forall u \in V \\
x(\delta(S)) \geq 2 & \forall S \subset V, 2 \leq|S| \leq|V|-1 \\
x_{e} \in\{0,1\} & \forall e \in E
\end{array}
$$

■ $\mathcal{P}^{\prime}=1$-Tree Relaxation: $O P T(c, 1-$ Tree $)$ in $O(m \log m)$

$$
\begin{array}{llll}
x(E) & = & |V| & \\
x(\delta(S)) \geq & 1 & \forall S \subset V, 2 \leq|S| \leq|V|-1 \\
x_{e} \in\{0,1\} & & \forall e \in E
\end{array}
$$

■ $\mathcal{P}^{\prime}=2$-Matching Relaxation: $O P T(c, 2-$ Match $)$ in polynomial time

$$
\begin{array}{ll}
x(\delta(u))=2 & \forall u \in V \\
x_{e} \in\{0,1\} & \forall e \in E
\end{array}
$$

## Example - TSP

■ Separation of Subtour Inequalities:

$$
x(\delta(S)) \geq 2
$$

■ $S E P(x$, Subtour $)$, for $x \in \mathbb{R}^{n}$ can be solved in $O\left(|V|^{4}\right)$ (Min-Cut)

- $S E P(s, S u b t o u r)$, for $s$ a 2-matching, can be solved in $O(|V|)$
- Simply determine the connected components $C_{i}$, and set $S=C_{i}$ for each componenet (each gives a violation of 2).

- Example - TSP
- Example - TSP
- Example - TSP
- Price and Cut (Revisited)
- Decomp and Cut

DECOMP Framework

## Motivation

- In Relax and Cut, the solutions to the Lagrangian subproblem $s \in \mathcal{E}$ typically have some nice combinatorial structure. So, the cutting step in Relax and Cut $S E P(s, \mathcal{P})$, can be relatively easy as opposed to general separation.

■ Question: Can we take advantage of this in other contexts?
■ LP theory tells us that in order to improve the bound, it is necessary and sufficient to cut off the entire face of optimal solutions $F$.

- This condition is difficult to verify, so we typically use the necessary condition that the generated inequality be violated by some member of that face, $x \in F$.
- In the Cutting Plane Method, we search for inequalities that violate $x_{C P}^{t} \in F^{t}$, where $F^{t}$ is optimal face over $\mathcal{P}_{O}^{t} \cap \mathcal{Q}^{\prime \prime}$.
- In the Price and Cut Method, we search for inequalities that violate $x_{P C}^{t} \in F^{t}$, where $F^{t}$ is optimal face over $\mathcal{P}_{I}^{t} \cap \mathcal{P}_{O}^{t}$.

- Outline

Decomposition Methods

## Motivation

- Now, consider the following set

$$
\mathcal{S}(u, \alpha)=\left\{s \in \mathcal{E} \mid\left(c^{\top}-u^{\top} A^{\prime \prime}\right) s=\alpha\right\},
$$

■ Then, $\mathcal{S}\left(u_{D W}^{t}, \alpha_{D W}^{t}\right)$ is the set e.p.s with $r c(s)=0$ in the DW-LP master or the set of alternative optimal solutions to the Lagrangian subproblem.

Theorem $1 F^{t} \subseteq \operatorname{conv}\left(\mathcal{S}\left(u_{D W}^{t}, \alpha_{D W}^{t}\right)\right)$
■ Therefore, separation of $\mathcal{S}\left(u_{D W}^{t}, \alpha_{D W}^{t}\right)$ gives an alternative necessary and sufficient condition for an inequality to be improving.

- By convexity, it is clear that every improving inequality must violate at least one extreme point in the optimal decomposition.

Theorem 2 If $(a, \beta) \in \mathbb{R}^{(n+1)}$ is an improving then there must exist an $s \in \mathcal{D}=\left\{s \in \mathcal{E} \mid \lambda_{s}^{t}>0\right\}$ such that $a^{\top} s<\beta$

Theorem $3 \mathcal{D}=\left\{s \in \mathcal{E} \mid \lambda_{s}^{t}>0\right\} \subseteq \mathcal{S}\left(u_{P C}^{t}, \alpha_{P C}^{t}\right)$

- Theorems 1-3, along with the observation that structured separation can be relatively easy, motivates the following revised PC method.

## Price and Cut (Revisited)

- Theorems 1-3 give us an alternative necessary condition for finding improving inequalities. PC gives us the optimal decomposition $D=\left\{s \in \mathcal{E} \mid \lambda_{s}>0\right\}$.
- Key Idea: In the cutting subproblem, rather than (or in addition to) separating $x_{P C}^{t}$, separate each $s \in D$.
- The violated subtour found by separating the 2-Matching also violates the fractional point, but was found at little cost.

Decomposition Methods

Integrated Decomposition Methods

- Price and Cut
- Relax and Cut
- Structured Separation
- Example - TSP
- Example - TSP
- Example - TSP
- Motivation
- Motivation
- Price and Cut (Revisited)

## Decomp and Cut

- In the context of the traditional CPM, we can construct (inverse DW) the decomposition $\lambda$ from the current fractional solution $x_{C P}$ by solving the following LP

$$
\max _{\lambda \in \mathbb{R}_{+}^{\mathcal{E}}}\left\{\mathbf{0}^{\top} \lambda: \sum_{s \in \mathcal{E}} s \lambda_{s}=x_{C P}, \sum_{s \in \mathcal{E}} \lambda_{s}=1\right\},
$$

- If we find a decomposition $\mathcal{D}$, then we separate each $s \in \mathcal{D}$, as in revised PC.
- If we fail, then the LP proof of infeasibility (Farkas Cut) gives us a separating hyperplane which can be used to cut off the current fractional point.

(a) $x_{C P} \in \mathcal{P}^{\prime}$

(b) $x_{C P} \notin \mathcal{P}^{\prime}$

## DECOMP Framework

■ DECOMP provides a flexible software framework for testing and extending the theoretical framework presented thus far, with the primary goal of minimal user responsibility.

- DECOMP was built around data structures and interfaces provided by COIN-OR: COmputational INfrastructure for Operations Research.

■ BCP provides a framework for parallel implementation of PC in a branch and bound framework with LP-Based Bounding.
■ A generalization of BCP currently under development:

- ALPs: Abstract Library for Parallel Search
- BiCePS: Branch, Constrain and Price [Generic Bounding]
- BLIS: BiCePS Linear Integer Solver = BCP

■ DECOMP could provide an implementation of the BiCePS layer.

- Outline

Decomposition Methods

- Algorithms Interface
- Applications Under Development - Summary

## DECOMP Framework

■ The framework, written in C++, is accessed through two user interfaces:

- Applications Interface: DecompApp
- Algorithms Interface: DecompAlgo
- One important feature of DECOMP is that the user only needs to provide methods for their application in the original space ( $x$-space), rather than in the space of a particular reformulation.
■ This allows for users to consider cuts and variables in their most intuitive form and greatly simplifies the process of expansion into rows and columns.

■ Features:

- Automatic reformulation - row and column expansion in DW master, dualization and multiplier updates in RC, etc...
- One interface to all default algorithms: CPM/DC, DW, LD, PC, RC.
- Built on top of the COIN/OSI interface, so easily interchange LP solvers.
- Active LP compression, variable and cut pool management.
- Easily switch between relaxations (choice of $\mathcal{P}^{\prime}$ ).

## Applications Interface

- In order to develop an application, the user must derive the following methods/objects. All other methods have appropriate defaults but are virtual and may be overridden.
- DecompApp: :createCore(). Define $\left[A^{\prime \prime}, b^{\prime \prime}\right]$.
- DecompVar. Define a variable $s \in \mathcal{F}^{\prime}$ in terms of $x$-space.
- DecompCut. Define a cut $(a, \beta)$ in terms of $x$-space.
- DecompApp::solveRelaxedProblem(). Provide a subroutine for $O P T\left(c, \mathcal{P}^{\prime}\right)$, given a cost vector $c$, that returns a set of solutions as DecompVar objects $\in \mathcal{F}^{\prime}$.
- DecompApp: :generateCuts (s). Provide a subroutine $\operatorname{SEP}(s, \mathcal{P})$, given a DecompVar $\in \mathcal{F}^{\prime}$, that returns a set of DecompCut objects.
■ If the user wishes to do traditional CPM or PC, they must also provide
- DecompApp: :generateCuts ( $x$ ). Provide a subroutine $S E P(x, \mathcal{P})$, given a arbitrary real vector, that returns a set of DecompCut objects.

## Applications Interface

- By default, DecompVar is a virtual object defined as a sparse vector of index/value assignments in $x$-space.
- For some applications, it is possible to more compactly represent a variable (many combinatorial problems). In this case, the user can derive APPDecompVar, which defines the assignment in $x$-space.
■ By default, DecompCut is a virtual object defined as a sparse vector if index/value assignments in $x$-space, and a right-hand side, $a^{\top} x \geq \beta$.
- For template cuts, it is often possible to more compactly represent a cut. In this case, the user can derive APPDecompCut, which defines the expansion of a cut in $x$-space.

## Algorithms Interface

■ The base class DecompAlgo provides the shell (master / subproblem) for integrated decomposition methods.
■ Each of the methods described have derived default implementations DecompAlgoX : public DecompAlgo.

■ New, hybrid or extended methods can be easily derived by overriding the various subroutines which are called from the base class. For example,

- Alternative methods for solving the master LP in DW, such as interior point methods or ACCPM.
- The user might choose to add a stabilizing factor to the dual updates in LD, as in bundle methods.
- The user might choose the Volume algorithm for solving the LD, which provides an approximation primal solution for which cuts can be generated.

- Summary

## Applications Under Development

- Steiner Tree Problem
- Minimum Spanning Tree : Lifted SECs, Partition - RC* [Lucena 92]
- Traveling Salesman Problem
- One-Tree: Blossoms, Combs
- Matching: SECs
- Vehicle Routing Problem
- k-Traveling Salesman Problem : GSECs - DC [Ralphs, et al. 03]
- k-Tree : GSECs, Combs, Multistars - RC* [Marthinhon, et al. 01]
- Axial Assignment Problem
- Assignment Problem : Clique-Facets - RC [Balas, Saltzman 91]

■ Knapsack Constrained Circuit Problem

- Knapsack Problem : Cycle Cover, Maximal-Set Inequalities
- Circuit Problem: Cycle Cover, Maximal-Set Inequalities

■ Edge-Weighted Clique Problem

- Tree Relaxation : Trees, Cliques - RC [Hunting, et al. 01]

■ Subtour Elimination Problem [G. Benoit / S. Boyd]

- Fractional 2-Factor Problem : SECs - DC / LP Context [Benoit, Boyd 03]

## Summary

■ Decomposition Methods approximate $\mathcal{P}$ as $\mathcal{P}^{\prime} \cap \mathcal{Q}^{\prime \prime}$, where $\mathcal{P}^{\prime}$ may have a large description.
■ Integrated Decomposition Methods optimize over $\mathcal{P}_{I} \cap \mathcal{P}_{O}$, where $\mathcal{P}_{I} \subset \mathcal{P}^{\prime}$ and $\mathcal{P}_{O} \supset \mathcal{P}$. Both polyhedra may have a large description.
■ Structured separation can be much easier than general separation.

- We gave some motivation for two new techniques: revised-PC and DC.
- The question remains: Empirically, how good are the cuts generated by separation of $s \in \mathcal{D}$ ?
- However, for some facet classes, it doesn't matter - we simply don't know how to separate $x \in \mathbb{R}^{n}$. These ideas provide a starting point.
■ DECOMP provides an easy-to-use framework for comparing and developing various decomposition-based methods.
- The code is open-source, currently released under CPL and will eventually be available through the COIN-OR project repository www.coin-or.org.
